

Five months ago, I shared the idea. Here's where it went.

So here's what I've been building.

- VibeFlow

The bottleneck in software just moved.

For thirty years, the hard part was writing the code. Now AI writes it in seconds.

The hard part is no longer writing it — it's trusting it.

Working-looking code is not the same as working code.

An AI hands you something plausible. The only question that matters is whether it's right — or just confident.

A single model is confidently wrong, with no second opinion and no record of why.

Don't trust one AI. Make three agree.

Claude, ChatGPT and Gemini review the same critical work
and must reach consensus before anything advances.

APPROVED

NEEDS_REVISION

REJECTED

HUMAN_APPROVAL_REQUIRED

Every verdict written to disk. No silent passes.
Now over CLIs, not MCP – a fraction of the cost.

- Requirements that can't be tested never become code.
- Every release decision is recorded — not felt.
- When the models disagree, a human decides.

Your code never leaves the building.

```
// 100% local – a plugin, not a SaaS  
// state lives as plain files in your Git  
// no database, no telemetry, no lock-in
```

“

I didn't build it to sell.

I built it on evenings, weekends and flights — the way I build most things. Not to prove anything. To keep my own judgment honest.

**We made code
cheap to write.
Now we make it
safe to trust.**

*How much would an AI have to prove before you'd
let it ship to production?*
